. A simple Go application with some basic authentication code and a PostgreSQL backend that implements the same API as GitHub's and GitLab's authentication work just fine and are much easier to reason about. It turns out PostgreSQL has a significant advantage over anything that uses true database-level security based on the password, meaning a password hash mechanism; (without having to use SSL or TLS). What is a password hash, anyway? A password hash means that when the user makes a request to the server they get a string that is uniquely generated from a password and the user's salt, which both are stored in plain text. A salted MD5 hash would look something like this: hvFbvKAG6jddK-5Zqz_r1MeUe84= The problem with these is that they contain a large amount of information about the password, including how many tries it took the user to guess the password, if the user guessed wrong, and the actual password (which is stored in plain text in the database). These are very inflexible and don't provide much in the way of security. The information is easily copied. The problem with a post-authentication hash is that it is easily broken by the addition of dictionary attack tools. This is the fundamental flaw with using a non-compliant hash. How does it work? It turns out that the post-authentication hash can be cracked to recover the password in one try by the addition of a salt. The salt, which is stored in plain text in the database, is used to create a unique encrypted value for the password which is stored in the database. The amount of time it takes for a user to guess a password by trial and error is proportional to the size of the salt, and how many characters the password has. The only way to stop the cracking would be to store the password and the salt separately, which would make the password hash useless, but it still can be used to authenticate a user into the system and stop other users from accessing the data for which the hash is the authentication method. Like this: Permit myself to indulge in a little fanboyism here. I think that when I first started reading about PostgreSQL for SQL Server over a decade ago, a new dimension was added to the proceedings. I remember being "unfairly" focused on

1. Field of the Invention The present invention relates to a plasma display panel (PDP). 2. Description of the Related Art A PDP is a display device that includes a pair of glass substrates, having discharge cells defined therebetween, and a phosphor layer formed on the inner surface of each of the glass substrates. Each of the discharge cells includes an address electrode, and is charged with a wall voltage generated when a predetermined discharge is produced in a discharge gas. The wall voltage causes a fluorescence agent placed in the discharge cells to generate visible light. When the visible light irradiates the phosphor layer, the phosphor layer generates secondary visible light. The intensity of the visible light depends on the quantity of the visible light which is generated by the secondary visible light. In general, for the purpose of display, the PDP is driven while maintaining a predetermined discharge state in the discharge cells. When a discharge for sustaining the discharge state in the discharge cells is insufficient, the discharge is deteriorated, or a mis-discharge occurs. The mis-discharge causes a density difference in the discharge cells. As a result, the display quality of the PDP deteriorates. One of factors that reduce the quantity of the discharge is a charging operation of the address electrode. The charging operation of the address electrode is performed after preliminary discharge, in which the address electrode is subjected to the preliminary discharge. When the preliminary discharge is insufficient, electric charges stored on the address electrode are insufficient. In the PDP, the address electrode is typically connected to a negative electrode terminal of a panel, and is configured to be in contact with a negative high voltage supply terminal (VW-) of the panel. If the address electrode of the PDP is connected to the negative high voltage supply terminal of the panel, the panel supplies a high voltage to the address electrode. Due to a direct contact between the negative high voltage supply terminal of

the panel and the address electrode, the PDP becomes an open-circuited state at the address electrode. If the PDP becomes the open-circuited state, a potential difference is generated between the negative high voltage supply terminal of the panel and the address electrode. A discharge is generated in the PDP in the following manner, and this phenomenon is referred to as addressing. The addressing generates a discharge in the discharge cell of the discharge cells. At this time, the discharge includes a light emission period during which the wall voltage is applied to the discharge cell, and a recovery period
